PROPIONAMIDE DERIVATIVES USEFUL AS ANDROGEN RECEPTOR MODULATORS

Technical field

The present invention relates to therapeutically active compounds and pharmaceutically acceptable salts and esters thereof useful in the treatment of nuclear receptor, especially steroid receptor, and in particular androgen receptor (AR) dependent conditions, and to pharmaceutical compositions containing such compounds. In particular, the invention discloses novel non-steroidal propionanilide structured compounds having utility as tissue-selective androgen receptor modulators (SARM). The compounds of the invention, which possess AR agonist activity, are useful in hormonal therapy, especially in treatment or prevention of conditions like male hypogonadism and age-related conditions such as andropause.

Background of the invention

Nuclear hormone receptors make up a family of ligand-inducible trancription factors whose members are involved in multiple physiological and developmental functions. During the last 20 years, more than sixty structurally and functionally related proteins belonging to this family have been identified. Nuclear hormone receptor family includes, in addition to classical steroid receptors (estrogen receptor, progesterone receptor, androgen receptor, glucocorticoid receptor and mineralo-corticoid receptor) also receptors e.g. for thyroid hormone, vitamin D and retinoids. Furthermore, a subclass of so-called orphan receptors for which no ligands have been identified up to date belong to this protein family. See Mangelsdorf et al, Cell (1995) 83(6): 835-839 and references therein. There exists an intense research directed to identify novel modulators for these proteins, ultimate goal thus being to find new therapies and treatment options for conditions and diseases modulated by nuclear/steroid receptors.

Steroidal androgens have been used for decades in the treatment of diseases resulting from deficiency in androgen action. They have also received attention for their use as hormone replacement therapy of aging men and in regulation of male fertility. However, current steroidal androgens, such as synthesized testosterone and its derivatives, have severe limitations. Testosterone is rapidly degraded by the liver

and thus has a low systemic bioavailability after oral administration. Further, orally available testosterone formulations, e.g. methyltestosterone, have been associated with alterations in liver function. Various other attempts have been made to overcome these drawbacks of steroidal androgens as therapeutic agents, but with limited success. Current testosterone formulations used in clinical practise include e.g. injections, patches and gels.

In recent years, there has been growing interest in the development of nonsteroidal modulators for steroid receptors for therapeutical use. It has been shown that nonsteroidal ligands can achieve better receptor selectivity and better physicochemical, pharmacokinetic and pharmacological properties. For androgen receptor (AR), nonsteroidal antagonists (antiandrogens) are now used clinically to counteract the undesirable actions of excessive androgens. In contrast, nonsteroidal AR agonists, which would have potential in the treatment of diseases resulting from androgen deficiency, have just recently been reported. Still, the structural elements of nonsteroidal ligands that would lead to optimal agonist activity and tissue selectivity are poorly defined.

Non-steroidal propionanilides having androgen receptor modulating activity have been described e.g. in patent publications EP 100172, EP 253503, WO 98/53826 and WO 02/16310. The design of propionanilide structured AR modulators has concentrated on compounds where the anilide ring is substituted by two electron-withdrawing substituents such as halogen, cyano, trifluoromethyl or nitro, since such substitution has been reported to enhance the androgen receptor binding affinity of the ligand. See e.g. Tucker, H. et al., J. Med. Chem., 1988, 31, 954-959.

Summary of the invention

It has now been found that compounds of formula (I) are potent nuclear receptor modulators, in particular androgen receptor modulators. Compounds of formula (I) show remarkably high affinity and activity in androgen receptor and possess utility as tissue-selective androgen receptor modulators (SARM). Compounds of formula (I), which possess AR agonist activity, have been found to be particularly suitable for use in hormonal therapy, especially in the treatment or prevention of conditions like male hypogonadism and age-related conditions such as andropause, e.g. for providing tissue-selective androgenic or anabolic effects. For

example, according to one preferred embodiment of the invention, the beneficial androgenic effects are obtained without concurrent harmful stimulation of the prostate. Compounds of the invention have generally also weak to moderate effect in the progesterone receptor, particularly antagonistic effect. It is conceived that concurrent progesterone antagonism may be beneficial as progesterone antagonism has been demonstrated to improve glucose tolerance in certain animal models. Compounds of the invention also provide good safety and sufficient water solubility.

The compounds of the present invention have a structure represented by formula (I)

EXPERIMENTS

Experiment 1. AR Binding Assay

Ventral prostates were obtained form rats castrated 24 h prior to sacrifice. Fresh prostate was minced and washed with Buffer A (Schilling and Liao, Prostate, 5:581-588, 1984). The minces were then homogenized in 3 x volume of Buffer A containing protease inhibitors (Complete, Mini, EDTA-free Roche). The homogenate was centrifuged at 30000g for 30 min. The resultant supernatants were treated with 1 x volume of dextran-coated charcoal solution (12,5 g activated charcoal, 12,5 g dextran per liter of buffer A) to remove endogenous steroids. The samples were incubated for 5 min and centrifuged at 16000g for 10 min. Aliquots of the charcoal-treated cytosol were taken for androgen receptor assays. All procedures were carried out at 0-4°C.

Cytosol androgen receptor concentration was determined as described (Isomaa et al., Endocrinology, 111: 833-843, 1982) with minor modifications. Cytosol preparations were prepared as described above, and bound and free steroids were separated by treatment with an equal volume of dextran-charcoal suspension for 5 min at 4°C followed by centrifugation at 16000g for 10 min. Bound radioactivity was determined by counting supernatant fractions in 1 ml of OptiPhase HiSafe3 or OptiPhase Supermix (PerkinElmer).

Cytosol preparations were labelled with 1 nM [^{3}H]-mibolerone overnight at 0°C (total). To determine AR binding activity of the compounds of the present invention (test compounds), the ability of test compounds to compete with [^{3}H]7α,17α-dimethyl-17β-hydroxy-4-estren-3-one ([^{3}H]-mibolerone) binding was studied. 1 nM [^{3}H]-mibolerone and test compounds in two concentrations (0,2 and 2 uM) were incubated overnight at 0°C. To determine non-specific binding, parallel incubations were carried out using 1 nM concentration [^{3}H]-mibolerone with 500-fold molar excess of unlabelled testosterone. Two to four replicates were used for each sample. After incubation, bound and free steroids were separated as described above and bound radioactivity was determined. The ability of the test compounds to bind AR is reported as reduction in bound radioactivity obtained with 1 nM [^{3}H]-mibolerone. The results are shown in Table 1. The results (% inhibition) were calculated as: % inhibition = 100 - (100x(average$_{\text{test compound}}$/average$_{\text{total}}$)).

Experiment 2. AR agonism and antagonism in immature male rats

The title compound of Example 3, abbreviated here as compound A, was further studied in *in vivo* experiment. The agonism and antagonism of the compound

with subcutaneous dosing was tested in immature male Spraque Dawley rat 3-day assay by analyzing the relative weights of ventral prostate, seminal vesicle, and *levator ani*-muscle. Testosterone propionate was used as a reference compound.

Testosterone propionate (abbreviated here TP) and compound A were first dissolved into DMSO and then into the vehicle sesame oil. Sprague-Dawley untreated male rats (18-19 days old) weighing about 50 g were used in the experiment. Rats were weighed and randomly distributed into five groups, with 5 animals per group (Table 1). Compound A (doses 2 and 20 mg/kg) and testosterone propionate (dose 5 mg/kg) were given subcutaneously (s.c.) into the neck/back of the animals at a constant volume of 100 microl dosing solution/animal/day. The animals were dosed once daily for three days, and clinical signs were recorded during dosing. At the end of the study, animals were weighed and anaesthetised by CO_2 asphyxiation. Ventral prostate, seminal vesicles, and *levator ani*-muscle were dissected out, chilled, and weighed. For statistical analysis, the weights of all organs were normalized to body weights, and analyzed for statistical significant difference by single-factor ANOVA.

Table 2. Animal groups and experimental design

Dose group & group number	Number of animals
1. Vehicle	5
2. Testosterone propionate (TP) 5mg/kg s.c.	5
3. Compound A, 2 mg/kg	5
4. Compound A, 20 mg/kg	5
5. TP 5 mg/kg + Compound A, 20 mg/kg s.c.	5

The results are shown in Figure 1. Compound A shows androgenic and anabolic activity. The relative weights of ventral prostate, seminal vesicle and *levator ani* -muscle increased significantly with administration of testosterone propionate. Compared with testosterone propionate, compound A showed tissue selectivity. At dose 20 mg/kg it clearly increased the relative weight of *levator ani*-muscle and significantly the relative weight of seminal vesicle, but only minimally the relative weight of the prostate. Furthermore, compound A showed significant antagonistic activity in seminal vesicle. Neither testosterone propionate nor compound A had any effect on the body weights (data not shown). In the Figure, "a" means agonism,

$p<0.01$ compared to vehicle group, "b" means antagonism, $p<0.05$ compared to testosterone group, bars represent mean ± SEM.

Box II Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. [X] Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

Although claims 9 to 11 are directed to a method of treatment of the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.

2. [ ] Claims Nos.:
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:

3. [ ] Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box III Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. [ ] As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.

2 [ ] As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.

3 [ ] As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:

4. [ ] No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

[ ] The additional search fees were accompanied by the applicant's protest.

[ ] No protest accompanied the payment of additional search fees.
